ABSTRACT

A nonaqueous electrolyte secondary cell comprises a rolled-up electrode unit composed of a positive electrode, a negative electrode and a separator interposed therebetween, and negative a current collector plate and a positive electrode current collector plate joined to the respective ends electrode unit. The negative electrode of the collector plate is joined to an edge of the negative electrode projecting at one of the opposite ends of the The collector plate has a two-layer electrode unit. structure comprising a copper layer made of copper or an alloy consisting predominantly of copper, and a madeof metal not forming metal layer a intermetallic compound with lithium and having a lower laser beam reflectivity than copper or an consisting predominantly of the metal. The collector plate has its copper layer contacted with the edge of the negative electrode and welded thereto with a laser beam.
